UTAH BEEF SUPPLY SAFE FROM BSE (mad cow disease)

“Utahns can be assured that our food safety system is working, and that bovine spongiform encephalopathy (BSE), or Mad Cow disease is not present in Utah.” Those are the comments from Utah Commissioner of Agriculture and Food, Cary G. Peterson following a USDA briefing regarding the discovery of one dairy cow infected with BSE in Washington State.

“The risk to human health is extremely low, considering that no specific risk material such as head, brain or spinal cord tissue from the Washington cow made it into the food system,” said State Veterinarian, Dr. Michael R. Marshall. Meat product from the cow was processed December 9, 2003, and distributed. That product has been identified and is under recall. For information on BSE and human health visit the Centers for Disease Control and Prevention web site: www.cdc.gov/travel/diseases/madcow.htm

As of today, the Washington State cow has not been officially confirmed as being infected with BSE. Final tests on the suspect tissue are underway at the World Reference Laboratory in England. Test results are expected within seven days. The case remains a presumed positive for BSE nonetheless.

The herd from which the infected cow originated is under quarantine and will undergo tests, as will any cow that came in contact with the infected animal.

The USDA has initiated a comprehensive epidemiological investigation working with state, public health, and industry counterparts to determine the source of the disease. USDA will also work with the Food and Drug Administration as they conduct animal feed investigations, the primary pathway for the spread of BSE.

“Despite this finding, we remain confident in the safety of our beef supply,” said U.S. Secretary of Agriculture, Ann M. Veneman . “The risk to human health from BSE is extremely low.”

Because the animal was non-ambulatory (downer) at slaughter, samples were taken Dec. 9 as part of USDA’s targeted BSE surveillance system. The samples were sent to USDA’s National Veterinary Services Laboratory in Ames, Iowa. Positive results were obtained by both histology (a visual examination of brain tissue via microscope) and immunohistochemistry (the gold standard for BSE testing that detects prions through a staining technique). Test results were returned on Dec. 22 and retested on Dec 23.

(more)

BSE is a progressive neurological disease among cattle that is always fatal. It belongs to a family of diseases known as transmissible spongiform encephalopathies. Also included in that family of illnesses is the human disease, variant Creutzfeldt-Jakob Disease (vCJD), which is believed to be caused by eating neural tissue, such as brain and spinal cord, from BSE-affected cattle. USDA has determined that the cow comes from a farm in Washington State and as part of the USDA response plan, the farm has been quarantined. After the animal was slaughtered, the meat was sent for processing and USDA's Food Safety and Inspection Service is working to determine the final disposition of products from the animal.
